

# Assignment for Week 3/4

First Part: Due 4nd February (midnight on Saturday)

Second Part: Due 7th February.

Reminder: Mid Term is on the 9th of February.

## Part 1

1. Define the transfer function
2. Knowing what you know about the different types of input signals, what kind of input is implied in the transfer function?
3. In class we discussed how the solution to a dynamical system could be spit into different responses, namely free, steady state and forced. The equation showed that the total response was a simple sum of these basic responses.

Explain **in one sentence** why the total response is a simple sum of the individual responses?

4. A given system has the following transfer function:

$$H(s) = \frac{2s + 4}{s^2 + 5s + 6}$$

- a) What is the denominator of the transfer function called?
- b) What are the roots of the denominator called ?
- c) Determine the roots of characteristic equation from the transfer function.
- d) What kind of dynamics would this system display if the state variable that corresponds to this transfer function was perturbed slightly away from the steady state?

- e) Roughly sketch the dynamics on a phase plot.
- f) Carry out a simulation to show that your dynamic prediction in question (d) and (e) matches the simulation results. In order to answer this question construct a system that has the same roots. You can do this empirically by using one of the software tools that were demonstrated in class, ie find a set of values to use in the  $\mathbf{A}$  matrix that gives the same roots. Build a simulation using this  $\mathbf{A}$  matrix, ie solve  $d\mathbf{x}/dt = \mathbf{A}\mathbf{x}$ .
- g) Implement your own Newton-Raphson algorithm to find one of the roots in the characteristic equation of  $H(s)$
5. In your last assignment you derived the transfer function for the following system:

$$X_0 \xrightarrow{v_1} y_1 \xrightarrow{v_2} y_2 \xrightarrow{v_3} X_1$$

Use the following rate laws:

$$v_1 = k_1 X_0 \quad v_2 = k_2 y_1 \quad v_3 = k_3 y_2$$

Use the following values  $X_0 = 10; k_1 = 2.3; k_2 = 4.5; k_3 = 0.5$

Using the Newton-Raphson algorithm to determine the steady state values for  $y_1$  and  $y_2$ . Since this system is more than one dimensional, the normal scaler version of the Newton-Raphson is insufficient. Instead the method needs to be recast as a matrix problem. Use Google to research the method for implementing the multidimensional version of the Newton-Raphson algorithm.

6. Given the following signal:

$$8tu(t) - 16(t - 0.5)u(t - 0.5)$$

a) Sketch the signal (manually or by software)

b) Derive the Laplace transform for this signal, you may use the Laplace transform tables to help you.

## Part 2

7. Figure 1 sketches a particular input signal, the squiggle in the middle of the plot represents a full cycle sine wave. Write out the expression you would use to represent this signal.  $y$  is the height of the signal at  $t = 0$ .  $a$  and  $b$  are the start and stop times for engaging and disengaging the sine wave. 8.

Figure 1:  $y$  is the height of the initial step,  $a$  and  $b$  mark the start and end of the sine wave

Consider the simple two reaction system:

where  $v_o$  is the input rate and  $k$  the first-order rate constant. This system has the following transfer function:

$$H(s) = \frac{1}{s + k}$$

- a) Apply a step function that has a height  $h$  and starts at time  $= a$  and stops at time  $= b$ . Derive the time-domain solution.
- b) Carry out a numerical simulation to show that the solution you derived matches the numerical simulation (Pick a suitable value for  $k$ ).
- c) Sketch the signal generated by the following input equation:

$$2t - 2(t - 12)u(t - 12)$$

- d) Apply this input to the same system,  $H(s)$ , and derive the time domain solution.
- e) Plot the output  $y_1$  and input function together to compare the input and output responses.

9. Consider the simplest nonlinear system, a two step pathway with the first step governed by an irreversible mass-action rate law and the second step by an irreversible Michaelis-Menten rate law. The pathway has a single species,  $x$  which is governed by the nonlinear differential equation:

$$\frac{dx}{dt} = k_1 X_o - \frac{Vm x}{Km + x}$$

The steady state level for  $x$  is denoted by  $x_o$  and the parameter,  $Vm$ , has a value of  $Vm_o$  at steady state.

- a) Linearize this differential equation around the steady state values,  $x_o$  and  $Vm_o$  to generate a linearized version of the differential equation.
- b) What is the meaning of the  $\frac{dx}{dt}$  term that is on the left-hand side of the linearized equation?
- c) Take the Laplace transform of the linearized equation and derive the time dependent solution of the linearized system.
- d) Does the solution you get in c) look familiar?

- e) Using the solution from c), confirm that if  $\delta Vm$  is zero that the system relaxes back to the original steady state, ie  $\delta x = 0$ .
- f) Using the solution from c), determine the steady state change in  $\delta x$  when we make a change in  $\delta Vm$  and no change to  $\delta x$ .
- g) Using the characteristic equation from the transfer function in c), make a statement about the stability of the system and the kind of dynamics you expect to see after a disturbance in  $\delta x$ .
- h) Run a simulation of the linearized and nonlinear systems. Carry out perturbation experiments in both systems by perturbing  $\delta x$  by differing amounts and looking at the relaxation dynamics. How well does the linear system capture the nonlinear model? With your knowledge of the Michaelis-Menten equation at what level should the species,  $x$  be relative to the enzyme's  $Km$  in order to increase the reliability of the linearized system?
